# A “Hands-on” Introduction to MPI

Tim Mattson

Human Learning Group.

[tgmatso@gmail.com](mailto:tgmatso@gmail.com)

\* The name “MPI” is the property of the MPI forum (<http://www.mpi-forum.org>).

# Outline

- 
- MPI and distributed memory systems
    - The Bulk Synchronous Pattern and MPI collective operations
    - Introduction to message passing
    - The diversity of message passing in MPI
    - Geometric Decomposition and MPI
    - Concluding Comments

# Programming Model for distributed memory systems

- Programs execute as a collection of processes.
  - Number of processes almost always fixed at program startup time
  - Local address space per node -- NO physically shared memory.
  - Logically shared data is partitioned over local processes.
- Processes communicate by explicit send/receive pairs
  - Synchronization is implicit by communication events.
  - MPI (Message Passing Interface) is the most commonly used API

# Parallel API's: MPI, the Message Passing Interface

## ***MPI: An API for Writing Applications for Distributed Memory Systems***

- A library of routines to coordinate the execution of multiple processes.
- Provides point to point and collective communication in Fortran, C and C++
- Unifies last 30 years of cluster computing and MPP\* practice

# How do people use MPI?

## The SPMD Design Pattern

A sequential program  
working on a data set

Replicate the program.  
Add glue code  
Break up the data

- A single program working on a decomposed data set.
- Use Node ID and numb of nodes to split up work between processes
- Coordination by passing messages.

# Running MPI programs

The programs **mpirun** or **mpiexec** are largely equivalent and are used to launch a job on the processes across a cluster. On our cluster, we'll use **mpiexec**

- MPI implementations include a way to start “P processes” on the system.
- For MPIch (the most common MPI implementation), this is done with the mpirun command:

> mpiexec -n P ./a.out

Run the program locally as P processes

- There are many options for mpiexec.

> mpiexec -hostfile hostfile -n P ./a.out

Run the program as P processes on the nodes from hostfile.

A hostfile has node names one to a line followed by a colon and the number of available processors

> mpiexec -h

Ask mpiexec for information about mpiexec options.

## Building and running MPI programs at PSFC

- Log in to a gpu node, one hour request for one node to compile:  
`srun --nodes=1 --ntasks=1 --time=01:00:00 --pty /bin/bash`
- Then compile  
`mpicc/mpif90/mpic++ -o program program.cc/f90/C`
- To run, exit current shell, then  
`srun --nodes=2 --ntasks-per-node=3 --time=00:01:00 ./program`
- Will run 6 processes over 2 nodes.

# Exercise: Hello world part 1

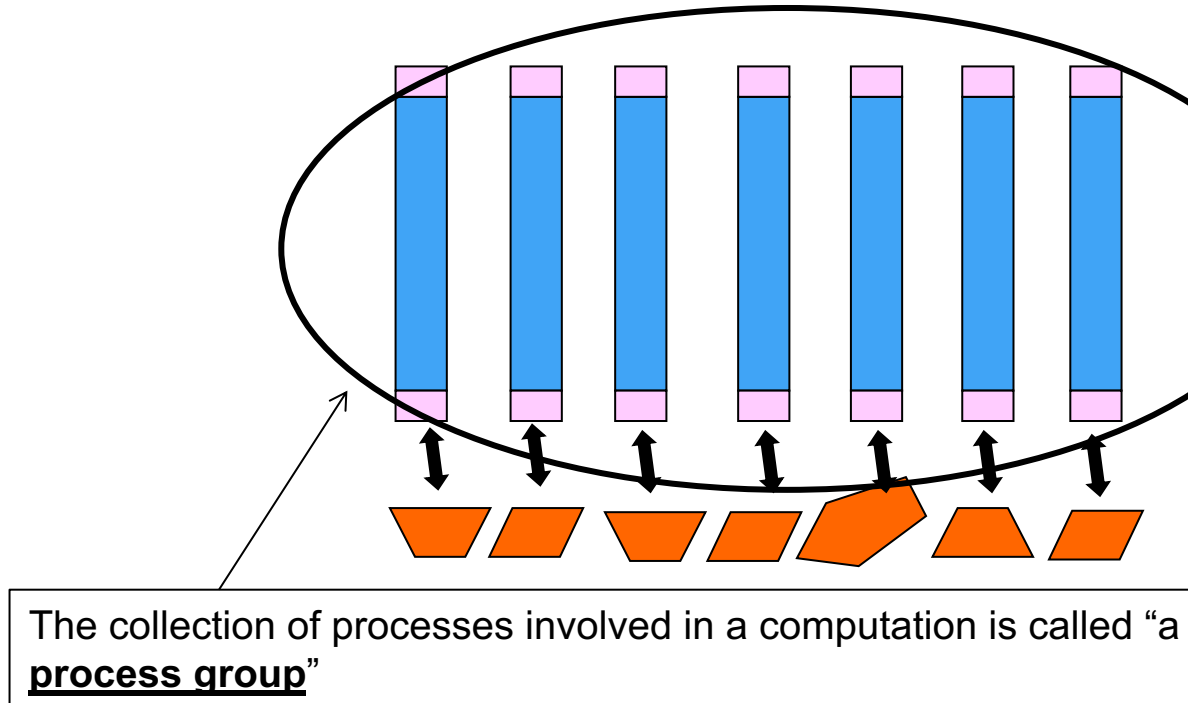

- Goal
  - To confirm that you can run a program in parallel.
- Program
  - Write a program that prints “hello world” to the screen.

- Log in to a the PSFC cluster. Compile and build the program on the log-in node
- Submit to run on the GPU cluster

```
srun --nodes=2 --ntasks-per-node=3 --time=00:01:00 ./program
```
- Will run 6 processes over 2 nodes

# An MPI program at runtime

- Typically, when you run an MPI program, multiple processes all running the same program are launched ... working on their own block of data.

# An MPI program at runtime

- Typically, when you run an MPI program, multiple processes all running the same program are launched ... working on their own block of data.

You can dynamically split a **process group** into multiple subgroups to manage how processes are mapped onto different tasks

# MPI Hello World Program

```
#include <stdio.h>
#include <mpi.h>
int main (int argc, char **argv){
    int rank, size;
    MPI_Init (&argc, &argv);
    MPI_Comm_rank (MPI_COMM_WORLD, &rank);
    MPI_Comm_size (MPI_COMM_WORLD, &size);
    printf( "Hello from process %d of %d\n",
           rank, size );

    MPI_Finalize();
    return 0;
}
```

# Initializing and finalizing MPI

```
int MPI_Init (int* argc, char* argv[])
```

- Initializes the MPI library ... called before any other MPI functions.
- argc and argv are the command line args passed from main()

```
#include <stdio.h>
#include <mpi.h>
int main (int argc, char **argv){
    int rank, size;
    MPI_Init (&argc, &argv);
    MPI_Comm_rank (MPI_COMM_WORLD, &rank);
    MPI_Comm_size (MPI_COMM_WORLD, &size);
    printf( "Hello from process %d of %d\n",
            rank, size );

    MPI_Finalize();
    return 0;
}
```

```
int MPI_Finalize (void)
```

- Frees memory allocated by the MPI library ... close every MPI program with a call to MPI\_Finalize

# How many processes are involved?

```
int MPI_Comm_size (MPI_Comm comm, int* size)
```

- `MPI_Comm`, an *opaque data type* called a *communicator*. Default context: `MPI_COMM_WORLD` (all processes)
- `MPI_Comm_size` returns the number of processes in the process group associated with the communicator

```
#include
```

```
#include <mpi.h>
```

```
int main (int argc, char **argv){
```

```
    int rank, size;
```

```
    MPI_Init (&argc, &argv);
```

```
    MPI_Comm_rank (MPI_COMM_WORLD, &rank);
```

```
    MPI_Comm_size (MPI_COMM_WORLD, &size);
```

```
    printf( "Hello from process %d of %d\n",  
           rank, size );
```

```
    MPI_Finalize();
```

```
    return 0;
```

```
}
```

**Communicators** consist of two parts, a **context** and a **process group**.

The communicator lets one control how groups of messages interact.

Communicators support modular SW ...  
i.e. I can give a library module its own communicator and know that its messages can't collide with messages originating from outside the module

# Which process “am I” (the rank)

```
int MPI_Comm_rank (MPI_Comm comm, int* rank)
```

- `MPI_Comm`, an *opaque data type*, a communicator. Default context: `MPI_COMM_WORLD` (all processes)
- `MPI_Comm_rank` An integer ranging from 0 to “(num of procs)-1”

```
#include <mpi.h>
int main (int argc, char **argv){
    int rank, size;
    MPI_Init (&argc, &argv);
    MPI_Comm_rank (MPI_COMM_WORLD, &rank);
    MPI_Comm_size (MPI_COMM_WORLD, &size);
    printf( "Hello from process %d of %d\n",
            rank, size );

    MPI_Finalize();
    return 0;
}
```

Note that other than `init()` and `finalize()`, every MPI function has a communicator.

This makes sense .. You need a context and group of processes that the MPI functions impact ... and those come from the communicator.

# Running the program

```
#include <stdio.h>
#include <mpi.h>
int main (int argc, char **argv){
    int rank, size;
    MPI_Init (&argc, &argv);
    MPI_Comm_rank (MPI_COMM_WORLD, &rank);
    MPI_Comm_size (MPI_COMM_WORLD, &size);
    printf( "Hello from process %d of %d\n",
           rank, size );

    MPI_Finalize();
    return 0;
}
```

- On a 4 node cluster, to run this program (hello):  
> mpiexec -np 4 -hostfile hostf hello
- Where “hostf” is a file with the names of the cluster nodes, one to a line.
- Would would this program output?

# Running the program

```
#include <stdio.h>
#include <mpi.h>
int main (int argc, char **argv){
    int rank, size;
    MPI_Init (&argc, &argv);
    MPI_Comm_rank (MPI_COMM_WORLD, &rank);
    MPI_Comm_size (MPI_COMM_WORLD, &size);
    printf( "Hello from process %d of %d\n",
           rank, size );

    MPI_Finalize();
    return 0;
}
```

- On a 4 node cluster, to run this program (hello):  
> mpiexec -np 4 -hostfile hostf hello  
Hello from process 1 of 4  
Hello from process 2 of 4  
Hello from process 0 of 4  
Hello from process 3 of 4
- Where “hostf” is a file with the names of the cluster nodes, one to a line.

# Exercise: Hello world part 2

- Goal

- To confirm that you can run an MPI program on our cluster

- Program

- Write a program that prints “hello world” to the screen.
- Modify it to run as an MPI program ... with each printing “hello world” and its rank

- Log in to a gpu node, one hour request for one node to compile:  
`srun --nodes=1 --ntasks=1 --time=01:00:00 --pty /bin/bash -l`
- Then compile  
`mpicc/mpif90/mpic++ -o program program.cc/f90/C`
- To run, exit current shell, then  
`srun --nodes=2 --ntasks-per-node=3 --time=00:01:00 ./program`
- Will run 6 processes over 2 nodes.

```
#include <mpi.h>
int size, rank, argc;  char **argv;
MPI_Init (&argc, &argv);
MPI_Comm_rank (MPI_COMM_WORLD, &rank);
MPI_Comm_size (MPI_COMM_WORLD, &size);
MPI_Finalize();
Char name[MPI_MAX_PROCESSOR_NAME];
int MPI_Get_processor_name( char *name, int *resultLen )
```

Get the  
name of  
the node  
you're  
running on

# Running the program

```
#include <stdio.h>
#include <mpi.h>
int main (int argc, char **argv){
    int rank, size;
    MPI_Init (&argc, &argv);
    MPI_Comm_rank (MPI_COMM_WORLD, &rank);
    MPI_Comm_size (MPI_COMM_WORLD, &size);
    printf( "Hello from process %d of %d\n",
           rank, size );

    MPI_Finalize();
    return 0;
}
```

- On a 4 node cluster, I'd run this program (hello) as:

> mpirun -n 4 hello

Hello from process 1 of 4

Hello from process 2 of 4

Hello from process 0 of 4

Hello from process 3 of 4

# Outline

- MPI and distributed memory systems

## • The Bulk Synchronous Pattern and MPI collective operations

- Introduction to message passing
- The diversity of message passing in MPI
- Geometric Decomposition and MPI
- Concluding Comments

# A typical pattern with MPI Programs

- Many MPI applications directly call few (if any) message passing routines. They use the following very common pattern:

- Use the Single Program Multiple Data pattern
- Each process maintains a local view of the global data
- A problem broken down into phases each of which is composed of two subphases:
  - Compute on local view of data
  - Communicate to update global view on all processes (collective communication).
- Continue phases until complete

This is a subset or the SPMD pattern sometimes referred to as the Bulk Synchronous pattern.

# Collective Communication: Reduction

```
int MPI_Reduce (void* sendbuf,  
               void* recvbuf, int count,  
               MPI_Datatype datatype, MPI_Op op,  
               int root, MPI_Comm comm)
```

Returns  
MPI\_SUCCESS  
if there were no  
errors

- **MPI\_Reduce** performs specified reduction operation (**op**) on the **count** values in **sendbuf** from all processes in communicator. Places result in **recvbuf** on the process with rank **root** only.

MPI Data Type*	C Data Type
MPI_CHAR	char
MPI_DOUBLE	double
MPI_FLOAT	float
MPI_INT	int
MPI_LONG	long
MPI_LONG_DOUBLE	long double
MPI_SHORT	short

Operation	Function
MPI_SUM	Summation
MPI_PROD	Product
MPI_MIN	Minimum value
MPI_MINLOC	Minimum value and location
MPI_MAX	Maximum value
MPI_MAXLOC	Maximum value and location
MPI_LAND	Logical AND

Operation	Function
MPI_BAND	Bitwise AND
MPI_LOR	Logical OR
MPI_BOR	Bitwise OR
MPI_LXOR	Logical exclusive OR
MPI_BXOR	Bitwise exclusive OR
User-defined	It is possible to define new reduction operations

\*This is a subset of available MPI types

# MPI\_REDUCE Example

```
#include <mpi.h>

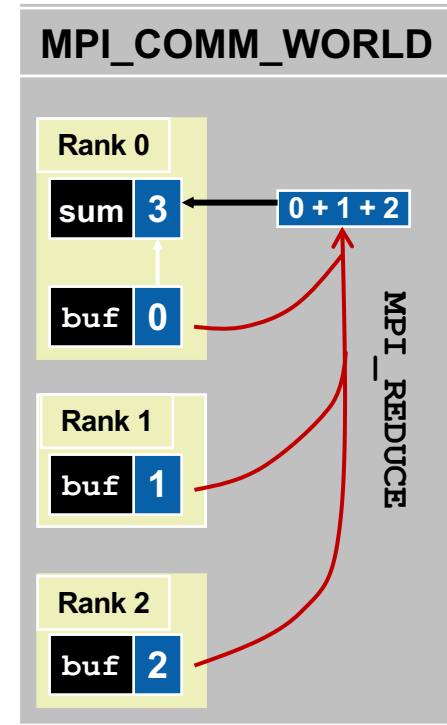

int main(int argc, char* argv[]) {
    int buf, sum, nprocs, myrank;

    MPI_Init(&argc, &argv);
    MPI_Comm_size(MPI_COMM_WORLD, &nprocs);
    MPI_Comm_rank(MPI_COMM_WORLD, &myrank);

    sum = 0;
    msg = myrank;

    MPI_Reduce(&buf, &sum, 1, MPI_INT,
               MPI_SUM, 0, MPI_COMM_WORLD);

    MPI_Finalize();
}
```

# MPI\_REDUCE Example

```
#include <mpi.h>

int main(int argc, char* argv[]) {
    int buf, sum, nprocs, myrank;

    MPI_Init(&argc, &argv);
    MPI_Comm_size(MPI_COMM_WORLD, &nprocs);
    MPI_Comm_rank(MPI_COMM_WORLD, &myrank);

    sum = 0;
```

## C language comments:

- **char\*** is a pointer to a collection of characters. We call this a string.
- **char\* argv[]** is the same as **char \*\*argv**. They point to a collection of strings
- If you have a variable, and you want its address, you use the **&** character. C is a call-by-value language. If you want to get new values from a function argument, you need to pass in the address, for example **&myrank**

# Example Problem: Numerical Integration

Mathematically, we know that:

$$\int_0^1 \frac{4.0}{(1+x^2)} dx = \pi$$

We can approximate the integral as a sum of rectangles:

$$\sum_{i=0}^N F(x_i) \Delta x \approx \pi$$

Where each rectangle has width  $\Delta x$  and height  $F(x_i)$  at the middle of interval  $i$ .

# PI Program: an example

```
static long num_steps = 100000;
double step;
void main ()
{   int i;       double x, pi, sum = 0.0;

    step = 1.0/(double) num_steps;
    x = 0.5 * step;
    for (i=0;i<= num_steps; i++){
        x+=step;
        sum += 4.0/(1.0+x*x);
    }
    pi = step * sum;
}
```

# Exercise: Pi Program

- Goal
  - To write a simple Bulk Synchronous, SPMD program
- Program
  - Start with the provided “pi program” and using an MPI reduction, write a parallel version of the program.

```
int MPI_Reduce (void* sendbuf, void* recvbuf, int count,  
               MPI_Datatype datatype, MPI_Op op,   int root, MPI_Comm comm)
```

MPI_Op	Function
MPI_SUM	Summation

```
#include <mpi.h>  
int size, rank, argc;  char **argv;  
MPI_Init (&argc, &argv);  
MPI_Comm_rank (MPI_COMM_WORLD, &rank);  
MPI_Comm_size (MPI_COMM_WORLD, &size);  
MPI_Finalize();
```

MPI Data Type	C Data Type
MPI_DOUBLE	double
MPI_FLOAT	float
MPI_INT	int
MPI_LONG	long

# Pi program in MPI

```
#include <mpi.h>
```

```
void main (int argc, char *argv[])
```

```
{
```

```
    int i, my_id, numprocs; double x, pi, step, sum = 0.0 ;
```

```
    step = 1.0/(double) num_steps ;
```

```
    MPI_Init(&argc, &argv) ;
```

```
    MPI_Comm_rank(MPI_COMM_WORLD, &my_id) ;
```

```
    MPI_Comm_size(MPI_COMM_WORLD, &numprocs) ;
```

```
    my_steps = num_steps/numprocs ;
```

```
    for (i=my_id*my_steps; i<(my_id+1)*my_steps ; i++)
```

```
    {
```

```
        x = (i+0.5)*step;
```

```
        sum += 4.0/(1.0+x*x);
```

```
    }
```

```
    sum *= step ;
```

```
    MPI_Reduce(&sum, &pi, 1, MPI_DOUBLE, MPI_SUM, 0, MPI_COMM_WORLD);
```

```
    ;
```

```
}
```

Sum values in “sum” from  
each process and place it  
in “pi” on process 0

# Timing MPI programs

- MPI added a function (which OpenMP copied) to time programs.
- **MPI\_Wtime()** returns a double for the time (in seconds) for some arbitrary time in the past.
- As with `omp_get_wtime()`, call before and after a section of code of interest to get an elapsed time.

# Exercise: Pi Program with MPI\_Wtime()

- Goal
  - Time your Bulk Synchronous, SPMD program
- Program
  - Start with your parallel “pi program” and use MPI\_Wtime() to explore its scalability on your system.

```
int MPI_Reduce (void* sendbuf, void* recvbuf, int count,  
               MPI_Datatype datatype, MPI_Op op,   int root, MPI_Comm comm)
```

MPI_Op	Function
MPI_SUM	Summation

```
#include <mpi.h>  
int size, rank, argc;  char **argv;  
MPI_Init (&argc, &argv);  
MPI_Comm_rank (MPI_COMM_WORLD, &rank);  
MPI_Comm_size (MPI_COMM_WORLD, &size);  
Double MPI_Wtime();  
MPI_Finalize();
```

MPI Data Type	C Data Type
MPI_DOUBLE	double
MPI_FLOAT	float
MPI_INT	int
MPI_LONG	long

# Pi program in MPI

```
#include <mpi.h>
void main (int argc, char *argv[])
{
    int i, my_id, numprocs; double x, pi, step, sum = 0.0 ;
    step = 1.0/(double) num_steps ;
    MPI_Init(&argc, &argv) ;
    MPI_Comm_rank(MPI_COMM_WORLD, &my_id) ;
    MPI_Comm_size(MPI_COMM_WORLD, &numprocs) ;
    double init_time = MPI_Wtime();
    my_steps = num_steps/numprocs ;
    for (i=my_id*my_steps; i<(my_id+1)*my_steps ; i++)
    {
        x = (i+0.5)*step;
        sum += 4.0/(1.0+x*x);
    }
    sum *= step ;
    MPI_Reduce(&sum, &pi, 1, MPI_DOUBLE, MPI_SUM, 0, MPI_COMM_WORLD);
    if(my_id == 0) printf(" runtime = %lf\n",MPI_Wtime()-init_time);
}
```

# MPI Pi program performance (on my laptop)

```
#include <mpi.h>
void main (int argc, char *argv[])
{
    int i, my_id, numprocs; double x, pi, step, sum = 0.0 ;
    step = 1.0/(double) num_steps ;
    MPI_Init(&argc, &argv) ;
    MPI_Comm_rank(MPI_COMM_WORLD, &my_id) ;
    MPI_Comm_size(MPI_COMM_WORLD, &numprocs) ;
    double init_time = MPI_Wtime();
    my_steps = num_steps/numprocs ;
    for (i=my_id*my_steps; i<(my_id+1)*my_steps ; i++)
    {
        x = (i+0.5)*step;
        sum += 4.0/(1.0+x*x);
    }
    sum *= step ;
    MPI_Reduce(&sum, &pi, 1, MPI_DOUBLE, MPI_SUM, 0, MPI_COMM_WORLD);
    if(my_id == 0) printf(" runtime = %lf\n",MPI_Wtime()-init_time);
}
```

Thread or procs	OpenMP SPMD critical	OpenMP PI Loop	MPI
1	0.85	0.43	0.84

    {
        x = (i+0.5)*step;
        sum += 4.0/(1.0+x*x);
    }
    sum *= step ;
    MPI_Reduce(&sum, &pi, 1, MPI_DOUBLE, MPI_SUM, 0, MPI_COMM_WORLD);
    if(my_id == 0) printf(" runtime = %lf\n",MPI_Wtime()-init_time);
}
```

Thread or procs	OpenMP SPMD critical	OpenMP PI Loop	MPI
1	0.85	0.43	0.84
2	0.48	0.23	0.48
3	0.47	0.23	0.46
4	0.46	0.23	0.46

Is this a dependable way to get an elapsed time?

What if instead of a laptop, we are starting processes across a large cluster? Is this time reliable?

\*Intel compiler (icpc) with -O3 on Apple OS X 10.7.3 with a dual core (four HW thread)  
Intel® Core™ i5 processor at 1.7 Ghz and 4 Gbyte DDR3 memory at 1.333 Ghz.

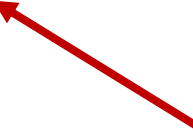

# Synchronization in MPI

- Synchronization ... establishing ordering constraints among concurrent processes so we can establish happens-before relations.
- As we will see later ... the semantics of how messages are passed includes synchronization properties.
- For a stand-alone synchronization construct, we can use a barrier (all processes in the group associated with comm arrive before any proceed):
  - `int MPI_Barrier(MPI_Comm comm)`

# Synchronization in MPI

- Synchronization ... establishing ordering constraints among concurrent processes so we can establish happens-before relations.
- As we will see later ... the semantics of how messages are passed includes synchronization properties.
- For a stand-alone synchronization construct, we can use a barrier (all processes in the group associated with comm arrive before any proceed):

`- int MPI_Barrier(MPI_Comm comm)`

What is this int for? All MPI routines other than the timing routines return an int error code. Equals MPI\_SUCCESS when everything is OK, other values specific to routines when errors occur

# Collective Communication: Reduction

```
int MPI_Reduce (void* sendbuf,  
               void* recvbuf, int count,  
               MPI_Datatype datatype, MPI_Op op,  
               int root, MPI_Comm comm)
```

Returns  
MPI\_SUCCESS  
if there were no  
errors

- **MPI\_Reduce** performs specified reduction operation (**op**) on the **count** values in **sendbuf** from all processes in communicator. Places result in **recvbuf** on the process with rank **root** only.

MPI_BXOR	Bitwise exclusive OR
User-defined	It is possible to define new reduction operations

\*This is a subset of available MPI types

# Timing without a barrier

- Another option ... forget the barrier. Collect times for all processes and report min, max and average. This is easy to do using the operations available for uwe in MPI\_Reduce.

```
int MPI_Reduce (void* sendbuf,  
               void* recvbuf, int count,  
               MPI_Datatype datatype, MPI_Op op,  
               int root, MPI_Comm comm)
```

Operation	Function
MPI_SUM	Summation
MPI_PROD	Product
MPI_MIN	Minimum value
MPI_MINLOC	Minimum value and location
MPI_MAX	Maximum value
MPI_MAXLOC	Maximum value and location
MPI_LAND	Logical AND

# Exercise: Explore timing MPI programs with the Pi program

- Goal
  - Time your Bulk Synchronous, SPMD program
- Program
  - Use MPI\_Wtime(), MPI\_Barrier() and other methods explore timing for the pi program.

```
int MPI_Reduce (void* sendbuf, void* recvbuf, int count,  
               MPI_Datatype datatype, MPI_Op op,  int root, MPI_Comm comm)
```

```
#include <mpi.h>  
int size, rank, argc;  char **argv;  
MPI_Init (&argc, &argv);  
MPI_Comm_rank (MPI_COMM_WORLD, &rank);  
MPI_Comm_size (MPI_COMM_WORLD, &size);  
double MPI_Wtime();  
int MPI_Barrier();  
MPI_Finalize();
```

Operation	Function
MPI_SUM	Summation
MPI_PROD	Product
MPI_MIN	Minimum value
MPI_MINLOC	Minimum value and location
MPI_MAX	Maximum value
MPI_MAXLOC	Maximum value and location
MPI_LAND	Logical AND

# Pi program ... return max time

```
#include <mpi.h>
```

```
void main (int argc, char *argv[])
```

```
{    int i, my_id, numprocs; double x, pi, step, sum = 0.0, mxtime=0.0;
```

```
    step = 1.0/(double) num_steps ;
```

```
    MPI_Init(&argc, &argv) ;
```

```
    MPI_Comm_rank(MPI_COMM_WORLD, &my_id) ;
```

```
    MPI_Comm_size(MPI_COMM_WORLD, &numprocs) ;
```

```
    MPI_Barrier(MPI_COMM_WORLD);
```

```
    double init_time = MPI_Wtime();
```

```
    my_steps = num_steps/numprocs ;
```

```
    for (i=my_id*my_steps; i<(my_id+1)*my_steps ; i++) {
```

```
        x = (i+0.5)*step;
```

```
        sum += 4.0/(1.0+x*x);
```

```
    }
```

```
    sum *= step ;
```

```
    MPI_Reduce(&sum, &pi, 1, MPI_DOUBLE, MPI_SUM, 0, MPI_COMM_WORLD);
```

```
    double wtime = MPI_Wtime()-init_time
```

```
    MPI_Reduce(&wtime, &mxtime, 1, MPI_DOUBLE, MPI_MAX, 0, MPI_COMM_WORLD);
```

```
    if(my_id == 0) printf(" maximum time = %lf",mxtime);
```

```
}
```

**MPI defines a rich set of Collective operations**

# Collective Computations

**Reduction:** Take values on each P and combine them with an op (such as add) into a single value on one P.

**Scan:** Take values on each P and combine them with a scan operation and spread the scan array out among all P.

```
int MPI_Reduce(const void *sendbuf, void *recvbuf, int count, MPI_Datatype datatype, MPI_Op op, int root, MPI_Comm comm)
int MPI_Scan(const void *sendbuf, void *recvbuf, int count, MPI_Datatype datatype, MPI_Op op, MPI_Comm comm)
```

# Collective Data Movement

**Broadcast** a value from P0 (the root) and give a copy to P1, P2 and P3

MPI\_Bcast()

**Scatter** an array on P0 (the root) to P1, P2, and P3

MPI\_Scatter()

**Gather** values from P1, P2, and P3 into an array on P0 (the root)

MPI\_Gather()

```
int MPI_Bcast( void *buffer, int count, MPI_Datatype datatype, int root, MPI_Comm comm )
int MPI_Gather(const void *sendbuf, int sendcount, MPI_Datatype sendtype, void *recvbuf, int recvcount, MPI_Datatype recvtype, int root, MPI_Comm comm)
int MPI_Scatter(const void *sendbuf, int sendcount, MPI_Datatype sendtype, void *recvbuf, int recvcount, MPI_Datatype recvtype, int root, MPI_Comm comm)
```

# More Collective Data Movement

**Gather** a chunk from each P and put it into a single array. Each P gets a copy of the resulting array.

**All to All:** Take chunks of data on each P and spread them out among the corresponding arrays on each P

```
int MPI_Allgather(const void *sendbuf, int sendcount, MPI_Datatype sendtype, void *recvbuf, int recvcount, MPI_Datatype recvtype, MPI_Comm comm)
int MPI_Alltoall(const void *sendbuf, int sendcount, MPI_Datatype sendtype, void *recvbuf, int recvcount, MPI_Datatype recvtype, MPI_Comm comm)
```

# MPI Collective Routines

- Collective communications: called by all processes in the group to create a global result and share with all participating processes.
  - `Allgather`, `Allgatherv`, `Allreduce`, `Alltoall`, `Alltoallv`, `Bcast`, `Gather`, `Gatherv`, `Reduce`, `Reduce_scatter`, `Scan`, `Scatter`, `Scatterv`
- Notes:
  - `Allreduce`, `Reduce`, `Reduce_scatter`, and `Scan` use the same set of built-in or user-defined combiner functions.
  - Routines with the “**All**” prefix deliver results to all participating processes
  - Routines with the “**v**” suffix allow chunks to have different sizes
- Global synchronization is available in MPI through a barrier which blocks until all the processes in the process group associated with the communicator call it.
  - `MPI_Barrier( comm )`

**Collective operations are powerful ... use them when you can**

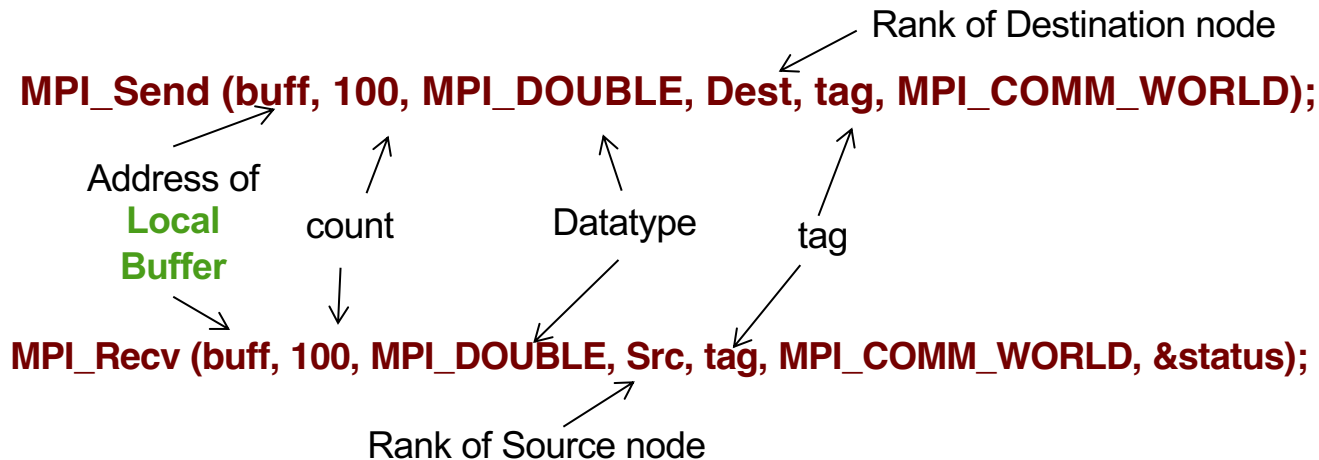

**Do not implement them from scratch on your own. Think about how you'd implement, for example, a reduction. It is MUCH harder to do than you might think**

# Outline

- MPI and distributed memory systems
- The Bulk Synchronous Pattern and MPI collective operations
-  • Introduction to message passing
- The diversity of message passing in MPI
- Geometric Decomposition and MPI
- Concluding Comments

# Sending and receiving messages

- Pass a buffer which holds “count” values of MPI\_TYPE
- The data in a message to send or receive is described by a triple:
  - **(address, count, datatype)**
- The receiving process identifies messages with the double :
  - **(source, tag)**
- Where:
  - Source is the rank of the sending process
  - Tag: a user-defined int to keep track of different messages from a single source

# Sending and Receiving messages: More Details

```
int MPI_Send (void* buf, int count,
              MPI_Datatype datatype, int dest,
              int tag, MPI_Comm comm)

int MPI_Recv (void* buf, int count,
              MPI_Datatype datatype, int source,
              int tag, MPI_Comm comm,
              MPI_Status* status)
```

**MPI\_Status** is a variable that contains information about the message that is received. We can use it to find out information about the received message. The most common usage is to find out how many items were in the message:

```
MPI_Status MyStat;    int count;    float buff[4];
int ierr = MPI_Recv(buf, 4, MPI_FLOAT, 2, 0, MPI_COMM_WORLD, &MyStat); // receive message from node=2 with message tag = 0
if(ierr == MPI_SUCCESS) MPI_Get_Count(MyStat, MPI_FLOAT, &count);
```

For messages of a known size, we typically ignore the status, in which case use the parameter `MPI_STATUS_IGNORE`

```
int ierr = MPI_Recv(&buff, 4, MPI_FLOAT, 2, 0, MPI_COMM_WORLD, MPI_STATUS_IGNORE);
```

# Sending and Receiving messages: More Details

```
int MPI_Send (void* buf, int count,
              MPI_Datatype datatype, int dest,
              int tag, MPI_Comm comm)

int MPI_Recv (void* buf, int count,
              MPI_Datatype datatype, int source,
              int tag, MPI_Comm comm,
              MPI_Status* status)
```

**MPI\_Status** is a variable that contains information about the message that is received. about the received message. The most common usage is to find out how many items v

```
MPI_Status MyStat;    int count;    float buff[4];
int ierr = MPI_Recv(buf, 4, MPI_FLOAT, 2, 0, MPI_COMM_WORLD, &MyStat); // receive message from node=2 with message tag = 0
If(ierr == MPI_SUCCESS) MPI_Get_Count(MyStat, MPI_FLOAT, &count);
```

## C language comments:

- **void\*** says the argument can take a pointer to any type. The C compiler won't do any type checking ... it just needs a valid address to a block of memory.
- A type with a \* means the function expects a pointer to that type. So I would declare a variable as **MPI\_Status MyStat** and then put the variable in the function call with an ampersand (&) ... for example **&MyStat**

For messages of a known size, we typically ignore the status, in which case use the parameter **MPI\_STATUS\_IGNORE**

```
int ierr = MPI_Recv(&buf, 4, MPI_FLOAT, 2, 0, MPI_COMM_WORLD, MPI_STATUS_IGNORE);
```

# MPI Data Types for C

MPI Data Type	C Data Type
MPI_BYTE	
MPI_CHAR	signed char
MPI_DOUBLE	double
MPI_FLOAT	float
MPI_INT	int
MPI_LONG	long
MPI_LONG_DOUBLE	long double
MPI_PACKED	
MPI_SHORT	short
MPI_UNSIGNED_SHORT	unsigned short
MPI_UNSIGNED	unsigned int
MPI_UNSIGNED_LONG	unsigned long
MPI_UNSIGNED_CHAR	unsigned char

MPI provides predefined data types that must be specified when passing messages.

# Exercise: Ping-Pong Program

- Goal
  - Measure the latency of our communication network.
- Program
  - Create a program to bounce a message (a single value) between a pair of processes. Bounce the message back and forth multiple times and report the average one-way communication time. Figure out how to use this so called “ping-pong” program to measure the latency of communication on your system.

```
int MPI_Send (void* buf, int count, MPI_Datatype datatype, int dest, int tag, MPI_Comm comm)

int MPI_Recv (void* buf, int count, MPI_Datatype datatype, int source, int tag,
              MPI_Comm comm, MPI_Status* status)
```

```
#include <mpi.h>
int size, rank, argc;  char **argv;
MPI_Init (&argc, &argv);
MPI_Comm_rank (MPI_COMM_WORLD, &rank);
MPI_Comm_size (MPI_COMM_WORLD, &size);
double MPI_Wtime();
MPI_Finalize();
```

MPI Data Type	C Data Type
MPI_DOUBLE	double
MPI_FLOAT	float
MPI_INT	int
MPI_LONG	long

# Solution: Ping-Pong Program

```
#include <mpi.h>
```

```
#include <stdio.h>
```

```
#include <stdlib.h>
```

```
#define VAL 42
```

```
#define NREPS 10
```

```
#define TAG 5
```

```
int main(int argc, char **argv) {
```

```
    int rank, size;
```

```
    double t0;
```

```
    MPI_Init(&argc, &argv);
```

```
    MPI_Comm_rank(MPI_COMM_WORLD, &rank);
```

```
    MPI_Comm_size(MPI_COMM_WORLD, &size);
```

```
    int bsend = VAL;
```

```
    int brecv = 0;
```

```
    MPI_Status stat;
```

```
    if(rank == 0) t0 = MPI_Wtime();
```

```
    for(int i=0;i<NREPS; i++){
```

```
        if(rank == 0){
```

```
            MPI_Send(&bsend, 1, MPI_INT, 1, TAG, MPI_COMM_WORLD);
```

```
            MPI_Recv(&brecv, 1, MPI_INT, 1, TAG, MPI_COMM_WORLD, &stat);
```

```
            if(brecv != VAL)printf("error: iteration %d %d != %d\n",i,brecv,VAL);
```

```
            brecv = 0;
```

```
        }
```

```
        else if(rank == 1){
```

```
            MPI_Recv(&brecv, 1, MPI_INT, 0, TAG, MPI_COMM_WORLD, &stat);
```

```
            MPI_Send(&bsend, 1, MPI_INT, 0, TAG, MPI_COMM_WORLD);
```

```
            if(brecv != VAL)printf("error: iteration %d %d != %d\n",i,brecv,VAL);
```

```
            brecv = 0;
```

```
        }
```

```
    }
```

```
    if(rank == 0){
```

```
        double t = MPI_Wtime() - t0;
```

```
        double lat = t/(2*NREPS);
```

```
        printf(" lat = %f seconds\n",(float)lat);
```

```
    }
```

```
    MPI_Finalize();
```

```
}
```

# Ping Pong for different message sizes ... but first a bit of C

- Input parameters from the command line (so you don't need to recompile for each case):

```
int main(int argc, char **argv)
{
    if (argc == 3){
        int msg_size = atoi(*++argv);
        int num_pings = atoi(*++argv);
    }
    else{
        int msg_size = 1;
        int num_pings = 10;
    }
}
```

Argc → number of command line arguments  
\*\*argv → Pointer to a set of strings

3 ... the executable Plus two args  
\*++argv ... increment to point to next string  
atoi() converts a string to an int

Define a default case for when you forget to include  
command line arguments

- Allocate memory and initialize buffer (i.e., a dynamic array of doubles)

```
double *msg = (double*)malloc(msg_size*sizeof(double));
for(int i; i<msg_size; i++) msg[i] = (double) i;
```

Malloc allocates memory  
as a void\*. Cast to the  
desired type

Msg is a pointer but we treat it like an array

# Command Line Arguments

- If I run my program like this:

```
./a.out 10 1000
```

- Then my program ping/pongs a message of size 1000 ten times.
- Is this enough? Will we be able to ping-pong messages driven by the command line with these changes?

# Exercise: Ping-Pong Program with command line args

- Goal
  - Measure the latency of our communication network for different sized messages.
- Program
  - Vary message sizes and number of pings/pongs from the command line.
  - Is it enough to process the command line arguments and malloc the memory?

```
int MPI_Send (void* buf, int count, MPI_Datatype datatype, int dest, int tag, MPI_Comm comm)

int MPI_Recv (void* buf, int count, MPI_Datatype datatype, int source, int tag,
              MPI_Comm comm, MPI_Status* status)
```

```
#include <mpi.h>
int size, rank, argc;  char **argv;
MPI_Init (&argc, &argv);
MPI_Comm_rank (MPI_COMM_WORLD, &rank);
MPI_Comm_size (MPI_COMM_WORLD, &size);
double MPI_Wtime();
MPI_Finalize();
```

```
int main(int argc, char **argv) {
    if (argc == 3){
        int msg_size = atoi(*++argv);
        int num_pings = atoi(*++argv);
    }
    double *msg = (double*)malloc(msg_size*sizeof(double));
    for(int i; i<msg_size; i++) msg[i] = (double) i;
```

## Hint: You need to do something more ...

- Problem

- The command line arguments are only visible on the node where the computation begins (rank 0).

- Solution

- Remember the broadcast operation ... from back when we discussed collective communication operations? You need to use that to send the command line inputs to the other node.

**Broadcast** a value from P0  
(the root) and give a copy to  
P1, P2 and P3

MPI\_Bcast()

```
int MPI_Bcast( void *buffer, int count, MPI_Datatype datatype, int root, MPI_Comm comm )
```

# Outline

- MPI and distributed memory systems
- The Bulk Synchronous Pattern and MPI collective operations
- Introduction to message passing
-  • The diversity of message passing in MPI
- Geometric Decomposition and MPI
- Concluding Comments

# Buffers

- Message passing is straightforward, but there are subtleties
  - Buffering and deadlock
  - Deterministic execution
  - Performance
- When you send data, where does it go? The following is the typical flow:

# Blocking Send-Receive Timing Diagram

(Receive before Send)

It is important to post the receive before sending, for highest performance.

# Exercise: Ring program

- Start with the basic ring program we provide.
- Study the code (ring.c and ring\_naive.c) and note how I manage the computation of where the message goes to and where it comes from for each node.
- Run it for a range of message sizes and notes what happens for large messages.

```
double *buff;    int buff_count, to, from, tag=3;  MPI_Status stat;  
  
MPI_Recv (buff, buff_count, MPI_DOUBLE, from, tag, MPI_COMM_WORLD, &stat);  
MPI_Send (buff, buff_count, MPI_DOUBLE, to,    tag, MPI_COMM_WORLD);
```

# Sources of Deadlocks

- Send a large message from process 0 to process 1
  - If there is insufficient storage at the destination NIC (Network Interface Unit), the send must wait for the user to provide the memory space (through a receive) to drain buffers inside the NIC
- What happens with this code?

Process 0	Process 1
<b>Send(to 1)</b>	<b>Send(to 0)</b>
<b>Recv(from 1)</b>	<b>Recv(from 0)</b>

- This code could deadlock ... it depends on the availability of system buffers in which to store the data sent until it can be received

## Some Solutions to the “deadlock” Problem

- Order the operations more carefully:

Process 0	Process 1
<b>Send (1)</b>	<b>Recv (0)</b>
<b>Recv (1)</b>	<b>Send (0)</b>

- Use a collective “swap” so buffers created when the communication operation is posted:

Process 0	Process 1
<b>Sendrecv (1)</b>	<b>Sendrecv (0)</b>

## More Solutions to the “unsafe” Problem

- Supply a sufficiently large buffer in the send function

Process 0	Process 1
<b>Bsend(1)</b>	<b>Bsend(0)</b>
<b>Recv(1)</b>	<b>Recv(0)</b>

- Use non-blocking operations:

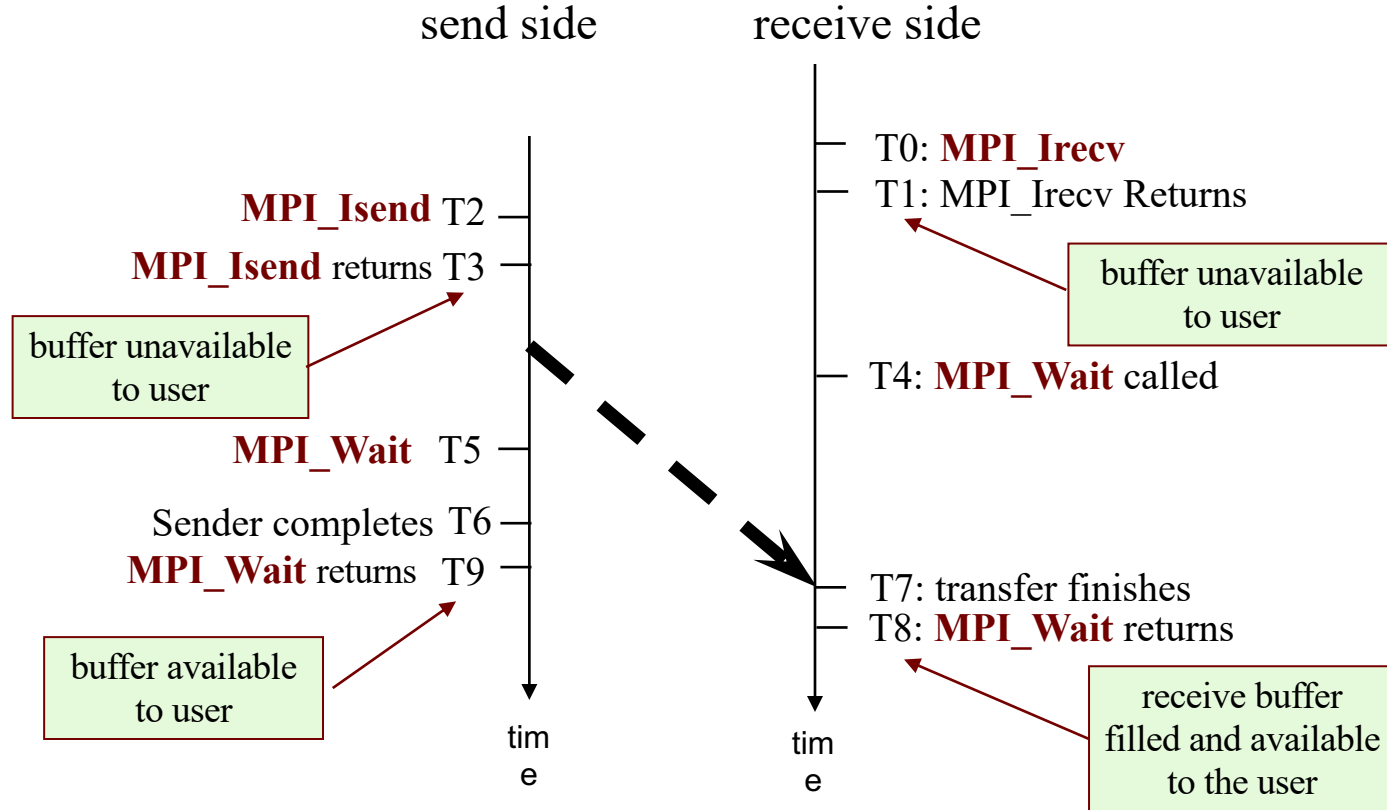

Process 0	Process 1
<b>Isend(1)</b>	<b>Isend(0)</b>
<b>Irecv(1)</b>	<b>Irecv(0)</b>
<b>Waitall</b>	<b>Waitall</b>

# Non-Blocking Communication

- Non-blocking operations return immediately and pass “request handles” that can be waited on and queried
  - **MPI\_Isend( start, count, datatype, dest, tag, comm, request )**
  - **MPI\_Irecv( start, count, datatype, src, tag, comm, request )**
  - **MPI\_Wait( request, status )**
- One can also test without waiting using **MPI\_TEST**
  - **MPI\_Test( request, flag, status )**
- Anywhere you use **MPI\_Send** or **MPI\_Recv**, you can use the pair of **MPI\_Isend/MPI\_Wait** or **MPI\_Irecv/MPI\_Wait**
- Note the MPI types:
  - MPI\_Status status;** // type used with the status output from recv
  - MPI\_Request request;** // the type of the handle used with isend/ircv

Non-blocking operations are extremely important ... they allow you to overlap computation and communication.

# Non-Blocking Send-Receive Diagram

## Exercise: Ring program

- Start with the basic ring program we provide. Run it for a range of message sizes and notes what happens for large messages.
  - It may deadlock if the network stalls due to there being no place to put a message (i.e. no receives in place so the send blocking on when its buffer can be reused hangs).
- Try to make it more stable for large messages by:
  - Split-phase ... have the nodes “send then receive” while the other half “receive then send”.
  - Sendrecv ... a collective communication send/receive.
  - Isend/Irecv ... nonblocking send receive

```
double *buff;    int buff_count, to, from, tag=3;  MPI_Status stat; MPI_Request request;

MPI_Recv (buff, buff_count, MPI_DOUBLE, from, tag, MPI_COMM_WORLD, &stat);
MPI_Send (buff, buff_count, MPI_DOUBLE, to,    tag, MPI_COMM_WORLD);
MPI_Isend( Buff, count, datatype, dest, tag, comm, &request )
MPI_Irecv( Buff, count, datatype, src, tag, comm, &request )
MPI_Wait( &request, &status )
MPI_Sendrecv (snd_buff, buff_count, MPI_DOUBLE, to, tag,
              rcv_buf,  buff_count, MPI_DOUBLE, to, tag, MPI_COMM_WORLD, &stat);
```

## Example: shift messages around a ring (part 1 of 2)

```
#include <stdio.h>
#include <mpi.h>

int main(int argc, char **argv)
{
    int num, rank, size, tag, next, from;
    MPI_Status status1, status2;
    MPI_Request req1, req2;

    MPI_Init(&argc, &argv);
    MPI_Comm_rank( MPI_COMM_WORLD, &rank);
    MPI_Comm_size( MPI_COMM_WORLD, &size);
    tag = 201;
    next = (rank+1) % size;
    from = (rank + size - 1) % size;
    if (rank == 0) {
        printf("Enter the number of times around the ring: ");
        scanf("%d", &num);

        printf("Process %d sending %d to %d\n", rank, num, next);
        MPI_Isend(&num, 1, MPI_INT, next, tag,
                  MPI_COMM_WORLD, &req1);

        MPI_Wait(&req1, &status1);
    }
}
```

```
do {
    MPI_Irecv(&num, 1, MPI_INT, from, tag,
              MPI_COMM_WORLD, &req2);

    MPI_Wait(&req2, &status2);

    if (rank == 0) {
        num--;
        printf("Process 0 decremented number\n");
    }

    printf("Process %d sending %d to %d\n", rank, num, next);
    MPI_Isend(&num, 1, MPI_INT, next, tag,
              MPI_COMM_WORLD, &req1);

    MPI_Wait(&req1, &status1);
} while (num != 0);

if (rank == 0) {
    MPI_Irecv(&num, 1, MPI_INT, from, tag,
              MPI_COMM_WORLD, &req2);

    MPI_Wait(&req2, &status2);
}
MPI_Finalize();
return 0;
}
```

# Outline

- MPI and distributed memory systems
- The Bulk Synchronous Pattern and MPI collective operations
- Introduction to message passing
- The diversity of message passing in MPI
-  • Geometric Decomposition and MPI
- Concluding Comments

# Example: finite difference methods

- Solve the heat diffusion equation in 1 D:
  - $u(x,t)$  describes the temperature field
  - We set the heat diffusion constant to one
  - Boundary conditions, constant  $u$  at endpoints.

$$\frac{\partial^2 u}{\partial x^2} = \frac{\partial u}{\partial t}$$

- map onto a mesh with stepsize  $h$  and  $k$

$$x_i = x_0 + ih \quad t_i = t_0 + ik$$

- Central difference approximation for spatial derivative (at fixed time)

$$\frac{\partial^2 u}{\partial x^2} = \frac{u_{j+1} - 2u_j + u_{j-1}}{h^2}$$

- Time derivative at  $t = t^{n+1}$

$$\frac{du}{dt} = \frac{u^{n+1} - u^n}{k}$$

## Example: Explicit finite differences

- Combining time derivative expression using spatial derivative at  $t = t^n$

$$\frac{u_j^{n+1} - u_j^n}{k} = \frac{u_{j+1}^n - 2u_j^n + u_{j-1}^n}{h^2}$$

- Solve for  $u$  at time  $n+1$  and step  $j$

$$u_j^{n+1} = (1 - 2r)u_j^n + ru_{j-1}^n + ru_{j+1}^n \quad r = k/h^2$$

- The solution at  $t = t_{n+1}$  is determined explicitly from the solution at  $t = t_n$  (assume  $u[t][0] = u[t][N] = \text{Constant}$  for all  $t$ ).

```
for (int t = 0; t < N_STEPS-1; ++t)
    for (int x = 1; x < N-1; ++x)
        u[t+1][x] = u[t][x] + r*(u[t][x+1] - 2*u[t][x] + u[t][x-1]);
```

- Explicit methods are easy to compute ... each point updated based on nearest neighbors. Converges for  $r < 1/2$ .

# Heat Diffusion equation

# Heat Diffusion equation

Pictorially, you are sliding a three point “stencil” across the domain ( $u[t]$ ) and computing a new value of the center point ( $u[t+1]$ ) at each stop.

# Heat Diffusion equation

```
int main()
{
    double *u    = malloc (sizeof(double) * (N));
    double *up1 = malloc (sizeof(double) * (N));
```

Note: I don't need the intermediate "u[t]" values hence "u" is just indexed by x.

```
    initialize_data(uk, ukp1, N, P); // initialize, set end temperatures
    for (int t = 0; t < N_STEPS; ++t){
        for (int x = 1; x < N-1; ++x)
            up1[x] = u[x] + (k / (h*h)) * (u[x+1] - 2*u[x] + u[x-1]);
```

```
        temp = up1; up1 = u; u = temp;
    }
    return 0;
```

A well known trick with 2 arrays so I don't overwrite values from step k-1 as I fill in for step k

# Heat Diffusion equation

```
int main()
{
    double *u    = malloc (sizeof(double) * (N));
    double *up1 = malloc (sizeof(double) * (N));

    initialize_data(uk, ukp1, N, P); // initialize, set end temperatures
    for (int t = 0; t < N_STEPS; ++t){
        for (int x = 1; x < N-1; ++x)
            up1[x] = u[x] + (k / (h*h)) * (u[x+1] - 2*u[x] + u[x-1]);

        temp = up1; up1 = u; u = temp;
    }
    return 0;
}
```

How would you  
parallelize this program?

# Exercise: Parallel heat diffusion

- Goal

- Parallelize the heat diffusion code (MPI\_Exercises/heat-eqn-seq.c) with OpenMP ... should be a quick and easy way to familiarize yourself with the code.
- As you do this, think about how you might parallelize this with MPI

```
#pragma omp parallel
#pragma omp for
#pragma omp critical
#pragma omp single
#pragma omp barrier
int omp_get_num_threads();
int omp_get_thread_num();
```

# Heat Diffusion equation

- Start with our original picture of the problem ... a one dimensional domain with end points set at a fixed temperature.

# Heat Diffusion equation

- Break it into chunks assigning one chunk to each process.

# Heat Diffusion equation

- Each process works on it's own chunk ... sliding the stencil across the domain to updates its own data.

# Heat Diffusion equation

- What about the ends of each chunk ... where the stencil will run off the end and hence have missing values for the computation?

# Heat Diffusion equation

- We add ghost cells to the ends of each chunk, update them with the required values from neighbor chunks at each time step ... hence giving the stencil everything it needs on any given chunk to update all of its values.

# Heat Diffusion MPI Example

```
MPI_Init (&argc, &argv);
MPI_Comm_size (MPI_COMM_WORLD, &P);
MPI_Comm_rank (MPI_COMM_WORLD, &myID);
double *u      = malloc (sizeof(double) * (2 + N/P)) // include "Ghost Cells"
double *up1 = malloc (sizeof(double) * (2 + N/P)); // to hold values
                                                    // from my neighbors

initialize_data(uk, ukp1, N, P);
for (int t = 0; t < N_STEPS; ++t){
    if (myID != 0) MPI_Send (&u[1], 1, MPI_DOUBLE, myID-1, 0, MPI_COMM_WORLD);
    if (myID != P-1) MPI_Recv (&u[N/P+1], 1, MPI_DOUBLE, myID+1, 0, MPI_COMM_WORLD, &status);
    if (myID != P-1) MPI_Send (&u[N/P], 1, MPI_DOUBLE, myID+1, 0, MPI_COMM_WORLD);
    if (myID != 0) MPI_Recv (&u[0], 1, MPI_DOUBLE, myID-1, 0, MPI_COMM_WORLD, &status);
```

```
    for (int x = 2; x < N/P; ++x)
        up1[x] = u[x] + (k / (h*h)) * (u[x+1] - 2*u[x] + u[x-1]);
    if (myID != 0)
        up1[1] = u[1] + (k / (h*h)) * (u[1+1] - 2*u[1] + u[1-1]);
    if (myID != P-1)
        up1[N/P] = u[N/P] + (k/(h*h)) * (u[N/P+1] - 2*u[N/P] + u[N/P-1]);
    temp = up1; up1 = u; u = temp;
```

```
} // End of for (int t ...) loop
```

```
MPI_Finalize();
return 0;
```

We write/explain  
this part first and  
then address the  
communication  
and data  
structures

# Heat Diffusion MPI Example

```
// Compute interior of each “chunk”
```

```
for (int x = 2; x < N/P; ++x)
```

```
    up1[x] = u[x] + (k / (h*h)) * (u[x+1] - 2*u[x] + u[x-1]);
```

Update array values using local data and values from ghost cells.

```
// update edges of each chunk keeping the two far ends fixed
```

```
// (first element on Process 0 and the last element on process P-1).
```

```
if (myID != 0)
```

```
    up1[1] = u[1] + (k / (h*h)) * (u[1+1] - 2*u[1] + u[1-1]);
```

$u[0]$  and  $u[N/P+1]$  are the ghost cells

```
if (myID != P-1)
```

```
    up1[N/P] = u[N/P] + (k/(h*h)) * (u[N/P+1] - 2*u[N/P] + u[N/P-1]);
```

```
// Swap pointers to prepare for next iterations
```

```
temp = up1; up1 = u; u = temp;
```

```
} // End of for (int t ...) loop
```

```
MPI_Finalize();
```

```
return 0;
```

Note I was lazy and assumed  $N$  was evenly divided by  $P$ . Clearly, I'd never do this in a “real” program.

# Heat Diffusion MPI Example

```
MPI_Init (&argc, &argv);
MPI_Comm_size (MPI_COMM_WORLD, &P);
MPI_Comm_rank (MPI_COMM_WORLD, &myID);
double *u      = malloc (sizeof(double) * (2 + N/P)) // include "Ghost Cells" to hold
double *up1 = malloc (sizeof(double) * (2 + N/P)); // values from my neighbors

initialize_data(uk, ukp1, N, P);
for (int t = 0; t < N_STEPS; ++t){
    if (myID != 0)
        MPI_Send (&u[1], 1, MPI_DOUBLE, myID-1, 0, MPI_COMM_WORLD);

    if (myID != P-1)
        MPI_Recv (&u[N/P+1], 1, MPI_DOUBLE, myID+1, 0, MPI_COMM_WORLD, &status);

    if (myID != P-1)
        MPI_Send (&u[N/P], 1, MPI_DOUBLE, myID+1, 0, MPI_COMM_WORLD);

    if (myID != 0)
        MPI_Recv (&u[0], 1, MPI_DOUBLE, myID-1, 0, MPI_COMM_WORLD, &status);
}
/* continued on previous slide */
```

1D PDE solver ... the simplest "real" message passing code I can think of. Note: edges of domain held at a fixed temperature

Send my "left" boundary value to the neighbor on my "left"

Receive my "right" ghost cell from the neighbor to my "right"

Send my "right" boundary value to the neighbor to my "right"

Receive my "left" ghost cell from the neighbor to my "left"

# The Geometric Decomposition Pattern

- This is an instance of a very important design pattern ... the Geometric decomposition pattern.

# Partitioned Arrays

- Realistic problems are 2D or 3D; require more complex data distributions.
- We need to parallelize the computation by partitioning this index space
- Example: Consider a 2D domain over which we wish to solve a PDE using an explicit finite difference solver . The figure shows a five point stencil ... update a value based on its value and its 4 neighbors.
- Start with an array  $\rightarrow$

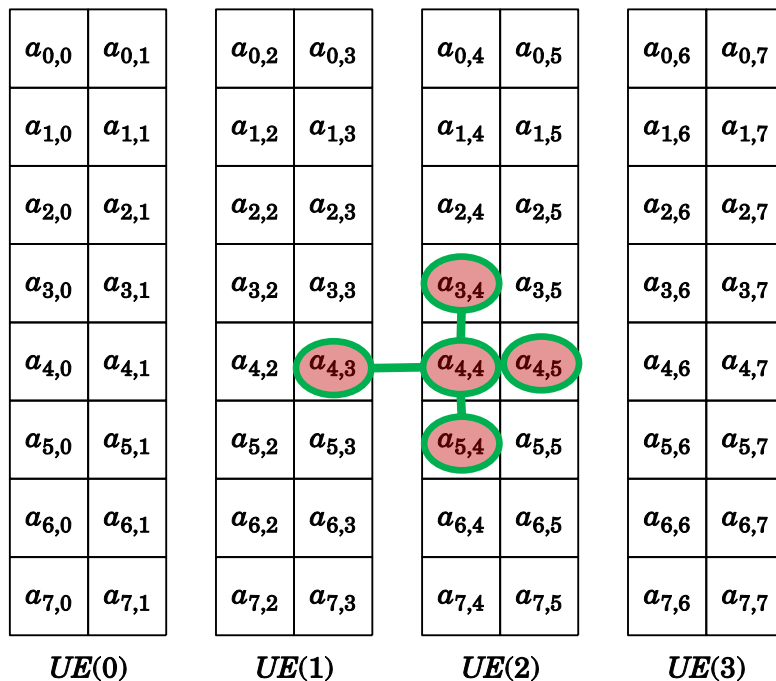

$a_{0,0}$	$a_{0,1}$	$a_{0,2}$	$a_{0,3}$	$a_{0,4}$	$a_{0,5}$	$a_{0,6}$	$a_{0,7}$
$a_{1,0}$	$a_{1,1}$	$a_{1,2}$	$a_{1,3}$	$a_{1,4}$	$a_{1,5}$	$a_{1,6}$	$a_{1,7}$
$a_{2,0}$	$a_{2,1}$	$a_{2,2}$	$a_{2,3}$	$a_{2,4}$	$a_{2,5}$	$a_{2,6}$	$a_{2,7}$
$a_{3,0}$	$a_{3,1}$	$a_{3,2}$	$a_{3,3}$	$a_{3,4}$	$a_{3,5}$	$a_{3,6}$	$a_{3,7}$
$a_{4,0}$	$a_{4,1}$	$a_{4,2}$	$a_{4,3}$	$a_{4,4}$	$a_{4,5}$	$a_{4,6}$	$a_{4,7}$
$a_{5,0}$	$a_{5,1}$	$a_{5,2}$	$a_{5,3}$	$a_{5,4}$	$a_{5,5}$	$a_{5,6}$	$a_{5,7}$
$a_{6,0}$	$a_{6,1}$	$a_{6,2}$	$a_{6,3}$	$a_{6,4}$	$a_{6,5}$	$a_{6,6}$	$a_{6,7}$
$a_{7,0}$	$a_{7,1}$	$a_{7,2}$	$a_{7,3}$	$a_{7,4}$	$a_{7,5}$	$a_{7,6}$	$a_{7,7}$

# Partitioned Arrays: Column block distribution

- Split the non-unit-stride dimension (P-1) times to produce P chunks, assign the  $i^{\text{th}}$  chunk to  $P_i$  .... To keep things simple, assume  $N\%P = 0$
- In a 2D finite-differencing program (exchange edges), how much do we have to communicate?  **$O(N/P)$  messages** per processor

**P** is the  
# of processors

**N** is the order of our  
square matrix

UE = unit of execution ... think of it as a generic term for “process or thread”

# Partitioned Arrays: Block distribution

- If we parallelize in both dimensions, then we have  $(N/p)^2$  elements per processor, and we need to send  $\sim 4 \cdot (n/p)$  **messages** from each processor. Asymptotically better than  $2 \cdot \sqrt{N}$ .

**P** is the  
# of processors

Assume a  $p$  by  $p$   
square mesh ...  
 $p = \sqrt{P}$

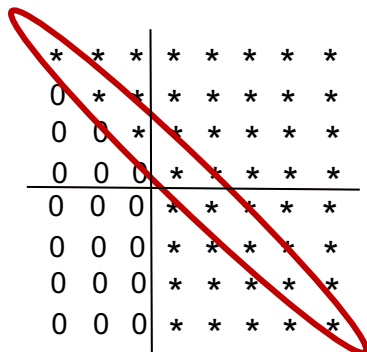

**N** is the order of our  
square matrix

Dimension of each  
block is  $N/P$

# Partitioned Arrays: block cyclic distribution

- LU decomposition ( $A = LU$ ) .. Move down the diagonal transform rows to “zero the column” below the diagonal.

*	*	*	*	*	*	*	*
0	*	*	*	*	*	*	*
0	0	*	*	*	*	*	*
0	0	0	*	*	*	*	*
0	0	0	*	*	*	*	*
0	0	0	*	*	*	*	*
0	0	0	*	*	*	*	*
0	0	0	*	*	*	*	*

- Zeros fill in the right lower triangle of the matrix ... less work to do.
- Balance load with cyclic distribution of blocks of  $A$  mapped onto a grid of nodes (2x2 in this case ... colors show the mapping to nodes).

# Matrix Transpose:

## Column block decomposition

You can only learn this stuff by doing it so we're going to design an algorithm to transpose a matrix using a partitioned array model based on column blocks.

Let's keep things simple. The order of A and B is N.  $N = \text{blk} * P$  where blk is the order of the square subblocks

# Matrix Transposition

We are going to create a transpose program that uses the SPMD pattern.

That's Single Program  
Multiple Data.

We'll run the same program on each node.

What is the high level structure of this algorithm?

That is ... how will each Processor march through its set of blocks?

Let's keep things simple.  $N = \text{blk} * P$  where blk is the order of the square subblocks

# Matrix Transposition

We are going to create a transpose program that uses the SPMD pattern.

That's Single Program Multiple Data.

We'll run the same program on each node.

What is the high level structure of this algorithm?

That is ... How will each Processor march through its set of blocks?

There is no one way to do this.

Since its an SPMD program, you want a symmetric path through the blocks on each processor.

A great approach is for everyone to start from their diagonal and shift down until they hit the bottom of their column.

Phase 0 ... transpose your diagonal

Let's keep things simple.  $N = \text{blk} * P$  where blk is the order of the square subblocks

# Matrix Transposition

We are going to create a transpose program that uses the SPMD pattern.

That's Single Program  
Multiple Data.

We'll run the same program on each node.

What is the high level structure of this algorithm?

That is ... How will each Processor march through its set of blocks?

Shift down (with a circular shift pattern ...  
i.e. when you run off an edge, wrap  
around to the opposite edge.

Phase 0 ... transpose your diagonal  
Phase 1 ... deal with next block "down"

Let's keep things simple.  $N = \text{blk} * P$  where blk is the order of the square subblocks

# Matrix Transposition

We are going to create a transpose program that uses the SPMD pattern.

That's Single Program  
Multiple Data.

We'll run the same program on each node.

What is the high level structure of this algorithm?

That is ... How will each Processor march through its set of blocks?

Shift down (with a circular shift pattern ...  
i.e. when you run off an edge, wrap  
around to the opposite edge.

Phase 0 ... transpose your diagonal  
Phase 1 ... deal with next block "down"

We know the sender ...  
who receives the block?

Let's keep things simple.  $N = \text{blk} * P$  where blk is the order of the square subblocks

# Matrix Transposition

We are going to create a transpose program that uses the SPMD pattern.

That's Single Program  
Multiple Data.

We'll run the same program on each node.

What is the high level structure of this algorithm?

That is ... How will each Processor march through its set of blocks?

Shift down (with a circular shift pattern ...  
i.e. when you run off an edge, wrap  
around to the opposite edge.

Phase 0 ... transpose your diagonal  
Phase 1 ... deal with next block "down"

We know the sender ...  
who receives the block?

Let's keep things simple.  $N = \text{blk} * P$  where  $\text{blk}$  is the order of the square subblocks

# Exercise: transpose program

- Start with the basic transpose program we provide (transpose.c and several trans\_\*.c functions).
- Your task ... deduce a general expression for the sender and receiver (FROM and TO) for each phase.
- Go to trans\_sendrcv.c and enter your definitions for the TO and FROM macros (what is there now is wrong ... I just wanted something to show how macros work).
- Test and verify correctness
- Try different message passing approaches.
- Can you overlap the local transpose and the communication between nodes?

```
double *buff;    int buff_count, to, from, tag=3;  MPI_Status stat, MPI_Request request;

MPI_Recv (buff, buff_count, MPI_DOUBLE, from, tag, MPI_COMM_WORLD, &stat);
MPI_Send (buff, buff_count, MPI_DOUBLE, to,    tag, MPI_COMM_WORLD);
MPI_Isend( Buff, count, datatype, dest, tag, comm, &request )
MPI_Irecv( Buff, count, datatype, src, tag, comm, &request )
MPI_Wait( &request, &status )
MPI_Sendrecv (snd_buff, buff_count, MPI_DOUBLE, to, tag,
              rcv_buf,  buff_count, MPI_DOUBLE, to, tag, MPI_COMM_WORLD, &stat);
```

# How do people mix MPI and OpenMP?

A sequential program  
working on a data set

**Replicate the program.**  
**Add glue code**  
**Break up the data**

- Create the MPI program with its data decomposition.
- Use OpenMP inside each MPI process.

# Pi program with MPI and OpenMP

Get the MPI part done first, then add OpenMP pragma where it makes sense to do so

```
#include <mpi.h>
#include "omp.h"
void main (int argc, char *argv[])
{
    int i, my_id, numprocs; double x, pi, step, sum = 0.0 ;
    step = 1.0/(double) num_steps ;
    MPI_Init(&argc, &argv) ;
    MPI_Comm_Rank(MPI_COMM_WORLD, &my_id) ;
    MPI_Comm_Size(MPI_COMM_WORLD, &numprocs) ;
    my_steps = num_steps/numprocs ;
    #pragma omp parallel for reduction(+:sum) private(x)
    for (i=my_id*my_steps; i<=(my_id+1)*my_steps ; i++)
    {
        x = (i+0.5)*step;
        sum += 4.0/(1.0+x*x);
    }
    sum *= step ;
    MPI_Reduce(&sum, &pi, 1, MPI_DOUBLE, MPI_SUM, 0,
    MPI_COMM_WORLD) ;
}
```

## Key issues when mixing OpenMP and MPI

1. Messages are sent to a process not to a particular thread.
  - Not all MPIs are threadsafe. MPI 2.0 defines threading modes:
    - MPI\_Thread\_Single: no support for multiple threads
    - MPI\_Thread\_Funneled: Mult threads, only master calls MPI
    - MPI\_Thread\_Serialized: Mult threads each calling MPI, but they do it one at a time.
    - MPI\_Thread\_Multiple: Multiple threads without any restrictions
  - Request and test thread modes with the function:  
`MPI_init_thread(desired_mode, delivered_mode, ierr)`
2. Environment variables are not propagated by mpirun. You'll need to broadcast OpenMP parameters and set them with the library routines.

# Dangerous Mixing of MPI and OpenMP

- The following will work only if MPI\_Thread\_Multiple is supported ... a level of support I wouldn't depend on.

```
MPI_Comm_Rank(MPI_COMM_WORLD, &mpi_id) ;
#pragma omp parallel
{
    int tag, swap_neigh, stat, omp_id = omp_thread_num();
    long buffer [BUFF_SIZE], incoming [BUFF_SIZE];
    big_ugly_calc1(omp_id, mpi_id, buffer);
                                                                    // Finds MPI id and tag so
    neighbor(omp_id, mpi_id, &swap_neigh, &tag); // messages don't conflict

    MPI_Send (buffer,  BUFF_SIZE, MPI_LONG, swap_neigh,
              tag, MPI_COMM_WORLD);
    MPI_Recv (incoming, buffer_count, MPI_LONG, swap_neigh,
              tag, MPI_COMM_WORLD, &stat);

    big_ugly_calc2(omp_id, mpi_id, incoming, buffer);
#pragma critical
    consume(buffer, omp_id, mpi_id);
}
```

# Messages and threads

- Keep message passing and threaded sections of your program separate:
  - Setup message passing outside OpenMP parallel regions (MPI\_Thread\_funneled)
  - Surround with appropriate directives (e.g. critical section or master) (MPI\_Thread\_Serialized)
  - For certain applications depending on how it is designed it may not matter which thread handles a message. (MPI\_Thread\_Multiple)
    - Beware of race conditions though if two threads are probing on the same message and then racing to receive it.

# Safe Mixing of MPI and OpenMP

## Put MPI in sequential regions

```
MPI_Init(&argc, &argv) ;    MPI_Comm_Rank(MPI_COMM_WORLD, &mpi_id) ;
```

```
// a whole bunch of initializations
```

```
#pragma omp parallel for
for (l=0;l<N;l++) {
    U[l] = big_calc(l);
}
```

```
    MPI_Send (U,  BUFF_SIZE, MPI_DOUBLE, swap_neigh,
              tag, MPI_COMM_WORLD);
    MPI_Recv (incoming, buffer_count, MPI_DOUBLE, swap_neigh,
              tag, MPI_COMM_WORLD, &stat);
```

```
#pragma omp parallel for
for (l=0;l<N;l++) {
    U[l] = other_big_calc(l, incoming);
}
```

```
consume(U, mpi_id);
```

**Technically Requires  
MPI\_Thread\_funneled, but I  
have never had a problem with  
this approach ... even with  
pre-MPI-2.0 libraries.**

# Safe Mixing of MPI and OpenMP

## Protect MPI calls inside a parallel region

```
MPI_Init(&argc, &argv);    MPI_Comm_Rank(MPI_COMM_WORLD, &mpi_id);
```

```
// a whole bunch of initializations
```

```
#pragma omp parallel
{
    #pragma omp for
        for (l=0;l<N;l++)    U[l] = big_calc(l);

    #pragma master
    {
        MPI_Send (U,  BUFF_SIZE, MPI_DOUBLE, neigh, tag, MPI_COMM_WORLD);
        MPI_Recv (incoming, count, MPI_DOUBLE, neigh, tag, MPI_COMM_WORLD, &stat);
    }
    #pragma omp barrier
    #pragma omp for
        for (l=0;l<N;l++)    U[l] = other_big_calc(l, incoming);

    #pragma omp master
        consume(U, mpi_id);
}
```

**Technically Requires  
MPI\_Thread\_funneled, but I  
have never had a problem with  
this approach ... even with  
pre-MPI-2.0 libraries.**

## Hybrid OpenMP/MPI works, but is it worth it?

- Literature\* is mixed on the hybrid model: sometimes its better, sometimes MPI alone is best.
- There is potential for benefit to the hybrid model
  - MPI algorithms often require replicated data making them less memory efficient.
  - Fewer total MPI communicating agents means fewer messages and less overhead from message conflicts.
  - Algorithms with good cache efficiency should benefit from shared caches of multi-threaded programs.
  - The model maps perfectly with clusters of SMP nodes.
- But really, it's a case by case basis and to large extent depends on the particular application.

\*L. Adhianto and Chapman, 2007

# Backup

- Mixing OpenMP and MPI

 • Loading MPI on your system

# MPIch library on Apple Laptops: MacPorts

- To use MPI on your Apple laptop:
  - Download Xcode. Be sure to choose the command line tools that match your OS.
  - Install MacPorts (if you haven't already ... use the installer for your OS from [macports.org](http://macports.org)).

```
sudo port selfupdate
```

Update to latest version of  
MacPorts

```
sudo port install mpich-gcc9
```

Grab the library that matches the  
version of your gcc compiler.

```
mpicc hello.c
```

Test the installation with a simple  
program

```
mpiexec -n 4 ./a.out
```
